Rania Haroon

Hello Lumen Ledger team,

Your ledger API turns payment events into a general ledger, and I've spent the last two years on the other side of that problem. At Tessellate Labs I built and still maintain the invoicing service that issues about 9,000 invoices a month, in Node.js, TypeScript and PostgreSQL.

The work I'm proudest of is boring on purpose. Our nightly reconciliation job took 41 minutes and had started overlapping the morning invoice run. I read the EXPLAIN output for a day, replaced row-by-row updates with set-based SQL, added two partial indexes, and got it to six minutes. At home I built ledger-lite, a small double-entry API where a Postgres constraint refuses any transaction whose debits and credits don't match. Someone on GitHub told me it caught a bug in their importer on day one.

You list AWS as a nice-to-have. I haven't used it in production; I moved four of our services to Docker Compose with health checks and wrote the runbook our on-call rotation uses, so containers and deploys aren't new to me, and I'm learning Kubernetes in the evenings.

If a junior engineer who likes the numbers to add up sounds useful, I'd be glad to talk.
